- ▶ Time Series Analysis and Its Applications with R Examples by Robert H. Shumway and David S. Stoffer

# Outline

- ▶ What is a time series? Time series model?
  - ▶ Time Series Examples
- ▶ Fundamental building blocks of time series
  - ▶ White noise
  - ▶ Moving average
  - ▶ Random walk
- ▶ Second order properties and stationarity
- ▶ When/why linear regression fails

# What is a Time Series?

A sequence of values of a variable at **equally spaced** intervals with a **natural temporal ordering**.

```
> require(astsa)
> window(jj, 1960, c(1965,4))
```

```
##      Qtr1 Qtr2 Qtr3 Qtr4
## 1960 0.71 0.63 0.85 0.44
## 1961 0.61 0.69 0.92 0.55
## 1962 0.72 0.77 0.92 0.60
## 1963 0.83 0.80 1.00 0.77
## 1964 0.92 1.00 1.24 1.00
## 1965 1.16 1.30 1.45 1.25
```

# What is a Time Series?

```
> plot(jj, type="o", ylab="Quarterly Earnings per Share")
```

# What is a Time Series?

```
plot(gtemp, type="o", ylab="Global Temperature Deviations")
```

# Key Assumption

Can't assume consecutive observations are independent

```
> jj_v <- unclass(jj)
> lag <- lag(jj_v, 1)
> lm <- lm(jj_v ~ lag)
> cor.test(~ jj_v + lag,
+         method = "pearson",
+         conf.level = 0.95)
```

```
##
## Pearson's product-moment correlation
##
## data:  jj_v and lag
## t = 25.987, df = 81, p-value < 2.2e-16
## alternative hypothesis: true correlation is not equal to 0
## 95 percent confidence interval:
##  0.9159239 0.9641248
## sample estimates:
##          cor
## 0.9449363
```

# Key Assumption

Can't assume consecutive observations are independent

```
> plot(jj_v, lag, ylab="lag(y)", xlab="y")
```

# Why Care about Time Series?

- ▶ They are everywhere!
- ▶ Economics (stock market, unemployment, etc)
- ▶ Social sciences (population series like birth rates or school enrollments)
- ▶ Epidemiology (influenza outbreaks)
- ▶ Medicine (blood pressure measurements)

# Working with Time Series

- ▶ Time series analysis
  - ▶ Analyzing observed data
  - ▶ Focus on characteristics of the data
  - ▶ Explanatory focus
- ▶ Time series forecasting
  - ▶ Generating a model
  - ▶ Predictive focus

# Some Additional Terminology

- ▶ Stochastic process
  - ▶ A sequence of random variables
  - ▶ Example: flipping a coin
- ▶ Sample path
  - ▶ Sample path of a stochastic process
  - ▶ One sample from a stochastic process
  - ▶ For example: HTHHTT (six coin flips)
- ▶ A stochastic process can generate MANY sample paths (infinitely many)

# Fundamental Stochastic Processes

- ▶ White noise
- ▶ Moving average
- ▶ Random walks

# White Noise

- ▶ Fundamental building block of other stochastic processes
- ▶ **Key:** NO correlation between observations
- ▶  $Y_t$  is called white noise (process looks like white light of spectrometers)

# White Noise: Definition

- ▶ Assume  $e_t \sim N(0, 1)$  is a collection of IID random variables all following a normal distribution
- ▶ Normal distribution? Anyone? Anyone at all?

Define  $Y_t = e_t$  for all  $t$

- ▶ A white noise process satisfies:
  - ▶  $\text{Mean}(Y_t) = \text{constant}$
  - ▶  $\text{Var}(Y_t) = \text{constant}$
  - ▶  $\text{Auto-covariance} = 0$

# White Noise: 1 Sample Path

# White Noise: Many Sample Paths

# White Noise: Implications

- ▶ Since the data is random there is no point in modeling

# Moving Average

- ▶ **Big difference:** there IS correlation between observations
- ▶ Assume  $e_t \sim N(0, 1)$  is a collection of IID random variables all following a normal distribution

Define 
$$Y_t = \frac{e_t + e_{t+1}}{2}$$
 for all  $t$

- ▶  $Y_t$  is a type of moving average stochastic process

# Moving Average: 1 Sample Path

# Moving Average: Many Sample Paths

# Random Walk

- ▶ Assume  $e_t \sim N(0, 1)$  is a collection of IID random variables all following a normal distribution

Define  $Y_t = e_1 + e_2 + \dots + e_t$  for all  $t$

- ▶  $Y_t$  is a random walk

# Random Walk: 1 Sample Path

# Random Walk: Many Sample Paths

# Why Care about Stochastic Processes?

- ▶ We have ONE sample path of observations
- ▶ From this sample path we intend to infer the stochastic process that generated it
- ▶ We are NOT fitting lines to the data
- ▶ We are understanding the sample paths the process could take

# Typical Process

- ▶ We observe a process to a specific point
- ▶ We determine what sample paths are likely as we look later in time

# Stationarity

- ▶ Heavily mathematical definition
- ▶ Essence of it:
  - ▶ The mean (or expected value of the stochastic process) is constant
  - ▶ Covariance (or correlation between points only depends on distance between points and not on the value of  $t$ )
- ▶ Stationarity is an extremely common assumption in time series modeling!

# Time Series: Linear Trend

- ▶ Assume stochastic process is  $Y_t = \beta_0 + \beta_1 t + X_t$
- ▶ Assume  $E[X_t] = 0$  and  $X_t$  is stationary
- ▶ This is just like linear regression so let's use OLS

# Time Series: Linear Trend

# Time Series

- ▶ Linear regression recovers the true parameters (close)

```
## # A tibble: 2 x 5
##   term          estimate std.error statistic  p.value
##   <chr>          <dbl>     <dbl>     <dbl>    <dbl>
## 1 (Intercept)    30.7      11.3       2.73 7.57e- 3
## 2 t              3.13      0.194     16.2 2.13e-29
```

# Time Series: Linear Model for Random Walk

- ▶ What if we fit a random walk  $Y_t$  with a linear model?
- ▶ Put another way: what if we regress a random walk on time with a linear model?
- ▶ Good choice, bad choice?

# Linear Model for a Random Walk

# Linear Model for a Random Walk

- ▶ Linear regression fails. Hard
- ▶ Significant trend when there is NOT one
- ▶ Reminder: there is not a trend because the expected value of  $Y_t$  is 0

```
## # A tibble: 2 x 5
##   term          estimate std.error statistic  p.value
##   <chr>          <dbl>    <dbl>    <dbl>    <dbl>
## 1 (Intercept)   -150.      22.9     -6.53 2.97e- 9
## 2 t              13.1      0.394     33.2 4.34e-55
```

# What Happened?

- ▶ Spurious regression
- ▶ DO NOT regress non-stationary time series
- ▶ Our mistake
  - ▶ Coefficient is okay
  - ▶ Standard error is underestimated
- ▶ A random walk does not follow required linear regression assumptions!
  - ▶ Which key assumption does it not follow?
